	QUESTION	ANSWER	WHAT THE EVIDENCE SHOWS
RQ1	Do EndorseRank and AWP differ, fit their own edges, and what do the walks cost?	H1, H3 supported H2 only narrowly	Largely by construction: most cohort contracts score zero under EndorseRank; the proxies come from the same events as the graphs; cost follows the layers walked (EndorseRank cheapest, C-PR slightly slower than AWP).
RQ2	Does a crawl ordered by C-PR reach the contracts with the most user-account demand sooner?	No · verdict V2 decides no rule	"Sooner than a breadth-first crawl, but not sooner than a crawl ordered by the number of contract backlinks." On user-authorized value the lead over breadth-first order is small and does not hold in every sensitivity. AWP' was the one single-layer walk sooner than its count; every crawl stayed far from the ideal order.
RQ3	Do frozen scores predict later labels, and does a walk beat the count it smooths?	Predict: yes Counts mostly win	The edge type decides which label a score anticipates. Against its count: EndorseRank below; AWP slightly above on the whole cohorts, below among W0 spenders that had received a transfer from another contract; C-PR above the union in-degree on approval pairs and below it on senders, and below the in-approve degree and the transfer in-degree on their labels.
RQ4	Does C-PR beat each of its layers walked alone?	No · rule A is not met	In W0 below its allowance layer on new approval pairs and below its transfer layer on new senders; in the same window outside the interval of the leading layer, and not above both layers on the stability family.
RQ5	Do allowances improve a transfer walk on new data?	No · rule B is not met	The two applied criteria of rule B, in W1: **F1 holds**, C-PR ranks new approval pairs above its transfer layer; **F2 fails**, its loss on new senders exceeds the margin.

Main question: on these data one walk over both edge types does not find the contracts that users rely on sooner, nor predict their later use better. Rules A and B are applied to the scores of the contract graph as a re-analysis; the registered analysis gave the same readings.
