Very many contracts
an address says nothing about the code behind it
The question that comes first
Which contracts do users rely on? This thesis ranks contracts by the relations between them.
It says where to apply the methods on the right first; it replaces none of them and predicts no exploit.
Risk layers each starts from a given protocol
Smart-contract risk
bugs in the code
Oracle risk
a stale price or a feed under someone's control
Market risk
volatility, liquidation cascades
Governance risk
voting power held by a few addresses
