

read on the contract graph's scores, as a re-analysis

Rule A, primary part (RQ4)
C-PR (λ = 0.5) no worse than C-PR (λ = 1) on new approval pairs, better than C-PR (λ = 0) on new transfer senders

Rule B, criteria F1 and F2 (RQ5)
against C-PR (λ = 0): F1, new approval pairs, interval above 0; F2, new transfer senders, lower end above $-\delta$

Two labels per spender, counting every account

New approval pairs: owner–spender pairs with a positive approval in the label window that were absent at the freeze.
New transfer senders: addresses that send the spender a transfer in the label window and had not since the score window began.

What is compared (RQ3)

Every score at the freeze against each label, Kendall τ_b with paired bootstrap intervals.
Each walk against the raw count of the edges it smooths: in-approve degree, transfer in-degree, union in-degree.
